Parallel programming languages on heterogeneous architectures using OPENMPC, OMPSS, OPENACC and OPENMP. *Revista Tecnura*, 18 (Edición especial doctorado), 160–170. doi: 10.14483/udistrital.jour.tecnura.2014.DSE1.a14

ABSTRACT

On the field of parallel programming has emerged a new big player in the last 10 years. The GPU's have taken a relevant importance on scientific computing because they offer a high performance computing, low cost and simplicity of implementation. However, one of the most important challenges is the programming languages used for these devices. The effort for recoding algorithms designed for CPUs is a critical problem. In this paper we review three of the principal frameworks for programming CUDA devices compared with the new directives introduced on the OpenMP 4 standard resolving the Jacobi iterative method.

Keywords: CUDA, Jacobi method, OmpSS, OpenACC, OpenMP, OpenMP, Parallel Programming.

RESUMEN

En el campo de la programación paralela, ha arribado un nuevo gran jugador en los últimos 10 años. Las GPU han tomado una importancia relevante en la computación científica debido a que ofrecen alto rendimiento computacional, bajo costos y simplicidad de implementación; sin embargo, uno de los desafíos más grandes que poseen son los lenguajes utilizados para la programación de los dispositivos. El esfuerzo de reescribir algoritmos diseñados originalmente para CPU es uno de los mayores problemas. En este artículo se revisan tres frameworks de programación para la tecnología CUDA y se realiza una comparación con el reciente estándar OpenMP versión 4, resolviendo el método iterativo de Jacobi.

Palabras clave: Método de Jacobi, OmpSS, OpenACC, OpenMP, Programación paralela.

INTRODUCTION

Since 10 years ago, the massively parallel processors have used the GPUs as principal element on the new approach in parallel programming; it's evolved from a graphics-specific accelerator to a general-purpose computing device and at this time is considered to be in the era of GPUs. (Nickolls & Dally, 2010). However, the main obstacle for large adoption on the programmer community has been the lack of standards that allow programming on unified form different existing hardware solutions (Nickolls & Dally, 2010). The most important player on GPU solutions is Nvidia® with the CUDA® language programming and his own compiler (nvcc) (Hill & Marty, 2008), with thousands of installed solutions and reward on top500 supercomputer list, while the portability is the main problem. Some community project and some hardware alliance have proposed solutions for resolve this issue. OmpSS, OpenACC and OpenMPC have emerged as the most promising solutions (Vetter, 2012) using the OpenMP base model. In the last year, OpenMP board released the version 4 (OpenMP, 2013) application program interface with support for external devices (including GPUs and Vector Processors). In this paper we compare the four implementation of Jacobi's factorization, to show the advantages and disadvantages of each framework.

METHODOLOGY

The frameworks used working as extensions of #pragmas of the C languages offering the simplest way to programming without development complicate and external elements. In the next section we describe the frameworks and give some implementations examples. In the last part, we show the pure CUDA kernels implementations.

Ompss

Ompss (a programming model from Barcelona Supercomputer center based on OpenMP and StarSs)

is framework focusses on task decomposition paradigm for developing parallel applications on cluster environments with heterogeneous architectures. It provides a set of compiler directives that can be used to annotate a sequential code. Additional features have been added to support the use of accelerators like GPUs. OmpSS is based on StartsS a task based programming model. It is based on annotating a serial application with directives that are translated by the compiler. With it, the same program that runs sequentially in a node with a single GPU can run in parallel in multiple GPUs either local (single node) or remote (cluster of GPUs). Besides performing a task-based parallelization, the runtime system moves the data as needed between the different nodes and GPUs minimizing the impact of communication by using affinity scheduling, caching, and by overlapping communication with the computational task.

OmpSs is based on the OpenMP programming model with modifications to its execution and memory model. It also provides some extensions for synchronization, data motion and heterogeneity support.

1) Execution model: OmpSs uses a thread-pool execution model instead of the traditional OpenMP fork-join model. The master thread starts the execution and all other threads cooperate executing the work it creates (whether it is from work sharing or task constructs). Therefore, there is no need for a parallel region. Nesting of constructs allows other threads to generate work as well (Figure 1).

2) Memory model: OmpSs assumes that multiple address spaces may exist. As such shared data may reside in memory locations that are not directly accessible from some of the computational resources. Therefore, all parallel code can only safely access private data and shared data which has been marked explicitly with our extended syntax. This assumption is true even for SMP machines as the implementation may reallocate shared data to improve memory accesses (e.g., NUMA).

3) Extensions:

Function tasks: OmpSs allows to annotate function declarations or definitions Cilk (Durán, Pérez, Ayguadé, Badia & Labarta, 2008), with a task directive. In this case, any call to the function creates a new task that will execute the function body. The data environment of the task is captured from the function arguments.

Dependency synchronization: OmpSs integrates the StarSs dependence support (Durán *et al.*, 2008). It allows annotating tasks with three clauses: input, output, in/out. They allow expressing, respectively, that a given task depends on some data produced before, which will produce some data, or both. The syntax in the clause allows specifying scalars, arrays, pointers and pointed data.

OpenACC

OpenACC is an industry standard proposed for heterogeneous computing on SuperComputer Conference 2011. OpenACC follows the OpenMP approach, with annotation on Sequential code with compiler directives (pragmas), indicating those regions of code susceptible to be executed in the GPU.

The execution model targeted by OpenACC API-enabled implementations is host-directed execution

with an attached accelerator device, such as a GPU. Much of a user application executes on the host. Compute intensive regions are offloaded to the accelerator device under control of the host. The device executes parallel regions, which typically contain work-sharing loops, or kernels regions, which typically contain one or more loops which are executed as kernels on the accelerator. Even in accelerator-targeted regions, the host may orchestrate the execution by allocating memory on the accelerator device, initiating data transfer, sending the code to the accelerator, passing arguments to the compute region, queuing the device code, waiting for completion, transferring results back to the host, and de-allocating memory (Figure 2). In most cases, the host can queue a sequence of operations to be executed on the device, one after the other (Wolfe, 2013).

The actual problems with OpenACC are relationship with the only for-join model support and support for only commercial compilers can support his directives (PGI, Cray and CAPS) (Wolfe, 2013; Reyes, López, fumero & Sande, 2012). In the last year, only one open source implementations has support (accULL) (Reyes & López-Rodríguez, 2012).

OpenMPC

The OpenMPC (OpenMP extendent for CUDA) is a framework to hide the complexity of programming model and memory model to user (Lee & Eigenmann, 2010). OpenMPC consists of a standard OpenMP API plus a new set of directives and environment variables to control important CUDA-related parameters and optimizations.

OpenMPC addresses two important issues on GP-GPU programming: programmability and tunability. OpenMPC as a front-end programming model provides programmers with abstractions of the complex CUDA programming model and high-level controls over various optimizations and CUDA-related parameters. OpenMPC included fully automatic compilation and user-assisted tuning system supporting OpenMPC. In addition to a range of compiler transformations and optimizations, the system includes tuning capabilities for generating, pruning, and navigating the search space of compilation variants.

OpenMPC use the compiler cetus (Dave, Bae, Min & Lee, 2009) for automatic parallelization source to source. The Source code on C has 3 level of analyzing

- Privatization
- Reduction Variable Recognition
- Induction Variable substitution

OpenMPC adding a numbers of pragmas for annotate OpenMP parallel regions and select optimization regions. The pragmas added has the following form: `#pragma cuda <<function>>`.

OpenMP release 4

OpenMP is the most used framework for programming parallel software with shared memory and support on most of the existing compilers. With the explosion of multicore and manycore system, OpenMP gains acceptance on parallel programming community and hardware vendors. From his creation to version 3 the focus of API was the CPUs environments, but with the introduction of GPUs and vector accelerators, the new 4 release includes support for external devices (OpenMP, 2013). Historically, OpenMP has support Simple Instruction Multiple Data (SIMD) model only focusses on fork-join model (Figure 3), but in this new release the task-base model (Duran *et al.*, 2008; Podobas, Brorsson & Faxén, 2010) has been introduced to gain performance with more parallelism on external devices. The most important directives introduced were target, teams and distributed. This directives permit that a group of threads was distributed on a special devices and the result was copied to host memory (Figure 3).

Figure 3. OpenMP 4 execution model

JACOBI ITERATIVE METHOD

Iterative methods are suitable for large scale linear equations. There are three commonly used iterative methods: Jacobi's method, Gauss method and SOR iterative methods (Gravvanis, Filelis-Papadopoulos & Lipitakis, 2013; Huang, Teng, Wahid & Ko, 2009).

The last two iterative methods convergence speed is faster than Jacobi's iterative method but lack of parallelism. They have advantages to Jacobi method only when implemented in sequential fashion and executed on traditional CPUs. On the other hand, Jacobi's iterative method has inherent parallelism. It's suitable to be implemented on CUDA or vector accelerators to run concurrently on many cores. The basic idea of Jacobi method is convert the system into equivalent system then we solved Equation (1) and Equation (2):

$$\begin{aligned} x = B \quad & a_{11}x_{11} + a_{12}x_2 + a_{13}x_3 = b_1 \\ & a_{21}x_{22} + a_{22}x_2 + a_{23}x_3 = b_2 \\ & a_{31}x_{33} + a_{32}x_2 + a_{33}x_3 = b_3 \end{aligned} \quad (1)$$

$$\begin{aligned} x_1 &= -\frac{a_{12}}{a_{11}}x_2 - \frac{a_{13}}{a_{11}}x_3 + \frac{b_1}{a_{11}} \\ x_2 &= -\frac{a_{21}}{a_{22}}x_1 - \frac{a_{23}}{a_{22}}x_3 + \frac{b_2}{a_{22}} \\ x_3 &= -\frac{a_{31}}{a_{33}}x_1 - \frac{a_{32}}{a_{33}}x_2 + \frac{b_3}{a_{33}} \end{aligned}$$

On each iteration we solve :

$$x_i^k = \frac{1}{a_{i,i}} \left[b_i - \sum_{j \neq i} a_{i,j} x_j^{k-1} \right] \quad (2)$$

Where the values from the $(k-1)$ iteration are used to compute the values for the k th iteration. The pseudo code for Jacobi method (Dongarra et al., 2008):

Choose an initial guest to the solution x .
for $k=1,2,\dots$

for $i=1,2,\dots,n$

$x_i=0$

for $j=1,2,\dots,i-1,i+1,\dots,n$

$x_i = x_i + a_{i,j}x_j^{(k-1)}$

end

$x_i = (b_i + x_i)/a_{i,i}$

end

$x^{(k)}=x$

check convergence; continue

if necessary

end

This iterative method can be implemented on a parallel form, using shared or distributed memory (Margaris, Souravlas & Roumeliotis, 2014) (Figure 4). For distributed memory, it needs some explicit synchronization and data out-process data copy. In share memory, it needs distribution and data merge in memory. It uses the following method:

$$x^{k+1} = D^{-1}(b - (L+U)x^k) \quad (3)$$

Figure 4. Parallel form of Jacobi method on shared memory (Alsemmeri, n.d.)

OPENMP IMPLEMENTATION

```
int n=LIMIT_N;
int m=LIMIT_M;
A[n][m]; // the D-1 matrix
```

```

Anew [n][m];
y_vector[n]; //b vector
//fill the matriz with initial conditions
...
#pragma omp parallel for shared (m, n, Anew,
A)
    for (int j = 1; j < n-1; j++)
    {
        for (int i = 1; i < m-1; i++)
        {
            Anew[j][i] = 0.25f * ( A[j][i+1] + A[j][i-1]
            + A[j-1][i] + A[j+1][i]);
            error = fmaxf( error, fabsf(Anew[j][i]-A[j]
[i]));
        }
    }
    #pragma omp parallel for shared (m, n,
Anew, A)
    for (int j = 1; j < n-1; j++)
    {
        for (int i = 1; i < m-1; i++)
        {
            A[j][i] = Anew[j][i];
        }
    }
    if (iter % 100 == 0) printf("%5d, %0.6f\n",
iter, error);
    iter++;
}
...//print the result

```

In this section, the for-joint model appears on section annotate with *#pragma omp parallel for shared (m, n, Anew, A)* where every threads (normally equals to cores) on system running a copy of code with different data section shared all variables named on *shared()* section. When the size of *m* and *n* is minor or equals to number of cores, the performance is similar on GPUs and CPUs, but when the size if much higher that number of cores available, the performance of GPUs increases because the parallelism level is higher (Fowers, Brown, Cooke & Stitt, 2012; Zhang, Miao, & Wang, 2009).

OPENACC IMPLEMENTATION

```

int n=LIMIT_N;
int m=LIMIT_M;
A[n][m]; // the D-1 matrix
Anew [n][m];
y_vector[n]; //b vector
//fill the matriz with initial conditions
...
#pragma omp parallel for shared (m, n, Anew,
A)
    #pragma acc kernels
    for( int j = 1; j < n-1; j++)
    {
        for( int i = 1; i < m-1; i++)
        {
            Anew[j][i] = 0.25f * ( A[j][i+1] + A[j][i-1]
            + A[j-1][i] + A[j+1][i]);
            error = fmaxf( error, fabsf(Anew[j][i]-A[j]
[i]));
        }
    }
    #pragma omp parallel for shared (m, n, Anew,
A)
    #pragma acc kernels
    for( int j = 1; j < n-1; j++)
    {
        for( int i = 1; i < m-1; i++)
        {
            A[j][i] = Anew[j][i];
        }
    }
    if(iter % 100 == 0) printf("%5d, %0.6f\n",
iter, error);
    iter++;
}
...//print the result

```

In this implementation appears a new annotation *#pragma acc kernels*, where it indicates that the code will be executed. This simple annotation hides a complex implementation of CUDA kernel, the copy of data from host to devices and devices to GPU and definition of grid of threads and the

data manipulation (Amorim & Haase, 2009; Sanders & Kandrot, 2011; Zhang *et al.*, 2009).

PURE CUDA IMPLEMENTATION (WANG, N.D.)

```
...
int dimB, dimT;
dimT = 256;
dimB = (dim / dimT) + 1;

float err = 1.0;

// set up the memory for GPU
float * LU_d;
float * B_d;
float * diag_d;
float * X_d, * X_old_d;
float * tmp;

    cudaMalloc( (void **) &B_d, sizeof(float) *
dim );
    cudaMalloc( (void **) &diag_d, sizeof(float)
* dim );
    cudaMalloc( (void **) &LU_d, sizeof(float) *
dim * dim);

    cudaMemcpy( LU_d, LU, sizeof(float) * dim *
dim, cudaMemcpyHostToDevice);
    cudaMemcpy( B_d, B, sizeof(float) * dim,
cudaMemcpyHostToDevice);
    cudaMemcpy( diag_d, diag, sizeof(float) *
dim, cudaMemcpyHostToDevice);

    cudaMalloc( (void **) &X_d, sizeof(float) *
dim);
    cudaMalloc( (void **) &X_old_d, sizeof(float)
* dim);
    cudaMalloc( (void **) &tmp, sizeof(float) *
dim);
...
//call to cuda kernels

// 2. Compute X by A x_old
```

```
    cudaMemcpy( X_old_d, x_old, sizeof(float)
* dim, cudaMemcpyHostToDevice);
    matMultVec<<<<dimB, dimT>>>>(LU_d, X_
old_d, tmp, dim, dim); // use x_old to compute
LU X_old and store the result in tmp
    substract<<<<dimB, dimT>>>>(B_d, tmp,
X_d, dim); // get the (B - LU X_old), which is
stored in X_d
    diaMultVec<<<<dimB, dimT>>>>(diag_d,
X_d, dim); // get the new X

    // 3. copy the new X back to the Host
Memory
    cudaMemcpy( X, X_d, sizeof(float) * dim,
cudaMemcpyDeviceToHost);

    // 4. calculate the norm of X_new - X_old
    substract<<<<dimB, dimT>>>>(X_old_d, X_d,
tmp, dim);
    VecAbs<<<<dimB, dimT>>>>(tmp, dim);
    VecMax<<<<dimB, dimT>>>>(tmp, dim);
    // copy the max value from Device to Host
    cudaMemcpy(max, tmp, sizeof(float),
cudaMemcpyDeviceToHost);
    // cuda kernel for vector multiplication
    __global__ void matMultVec(float * mat_A,
float * vec,
float * rst,
int dim_row,
int dim_col)
{
    int rowIdx = threadIdx.x + blockIdx.x *
blockDim.x; // Get the row Index
    int ald;
    while(rowIdx < dim_row)
    {
        rst[rowIdx] = 0; // clean the value at first
        for (int i = 0; i < dim_col; i++)
        {
            ald = rowIdx * dim_col + i; // Get the
index for the element a_{rowIdx, i}
            rst[rowIdx] += (mat_A[ald] * vec[i] ); // do
the multiplication
        }
    }
```

```

        rowIdx += gridDim.x * blockDim.x;
    }
    __syncthreads();
}

// cuda kernel for vector subtraction
__global__ void substract(float *a_d,
                        float *b_d,
                        float *c_d,
                        int dim)
{
    int tid = threadIdx.x + blockIdx.x * blockDim.x;
    while ( tid < dim )
    {
        c_d[tid] = a_d[tid] - b_d[tid];
        tid += gridDim.x * blockDim.x;
    }
}

__global__ void VecMax(float * vec, int dim)
{
    int tid = threadIdx.x + blockIdx.x * blockDim.x;
    while (dim > 1)
    {
        int mid = dim / 2; // get the half size
        if (tid < mid) // filter the active thread
        {
            if (vec[tid] < vec[tid+mid] ) // get the larger
one between vec[tid] and vec[tid+mid]
                vec[tid] = vec[tid+mid]; // and store the
larger one in vec[tid]
        }

        //deal with the odd case
        if (dim % 2 ) // if dim is odd...we need care
about the last element
        {
            if (tid == 0 ) // only use the vec[0] to com-
pare with vec[dim-1]
            {
                if (vec[tid] < vec[dim-1] )

```

```

        vec[tid] = vec[dim-1];
    }
}

__syncthreads(); // sync all threads
dim /= 2; // make the vector half size short.
}
}

```

The effort for writing three kernels, manage-
ment the logic of grids dimensions, copy data from
hosts to GPU and GPU to host, the aspect of syn-
chronization thread on the groups of Threads on
GPU and some aspects as ThreadID calculation
required high computation on hardware devices
and code programming.

TEST TECHNIQUE

We take the three implementations of Jacobi me-
thod (Pure OpenMP, OpenACC, OpenMPC) and
running it on SUT (System Under Test) of Table 1,
and make multiples running with square matri-
ces of incremental sizes (Table 2), take processing
time for analyzing the performance (Kim, n.d.;
Sun & Gustafson, 1991) against the code number
lines needed on the algorithm.

Table 1. Characteristics of System under Test

System	Supermicro SYS-1027GR-TRF
CPU	Intel® Xeon® 10-core E5-2680 V2 CPUs @ 2.80 GHz
Memory	32GB DDR3 1600MHz
GPU	NVIDIA Kepler K40 GPUs, 2880 Cuda Cores, Memory 12GB
OS	Red Hat Enterprise Linux Server release 6.4
Compiler	PGI Compiler Accelerator Fortran/C/C++ 14 release 9 for Linux
L2 Cache	256K
L3 Cache	25MB

Table 2. Matrix size performance comparison.

Matrix size (N)	Implementation	Mean Running Time (Seconds)
2048	OpenMP with 20 Threads	26.578
	OpenACC	74,970
	OpenMPC	69,890
4096	OpenMP with 20 Threads	74,280
	OpenACC	92,320
	OpenMPC	75,120
8096	OpenMP with 20 Threads	116,23
	OpenACC	98,00
	OpenMPC	101,420
16192	OpenMP with 20 Threads	522.320
	OpenACC	190,230
	OpenMPC	222,320

RESULT

The performance on the three frameworks (OpenMP v. 4, OpenACC, OpenMPC) presents a similar result on square matrices with size of 2048; however, if the size ingresses to 4096, the performance is little high on OpenACC implementation. With huge matrices greater than 12288, another factor as cache L2 and L3 has impact on process of data copy from host to device (Bader & Weidendorfer, 2009; Barragan & Steves, 2011; Gupta, Xiang, & Zhou, 2013). The performance of using a framework against using direct GPU CUDA languages, was just a bit (<5%), but the number of code lines was 70% minor. This shows that the framework offers useful programming tools with computational performance advantage; however, the performance gains on GPUs is on region of algorithms with high level of parallelism, and low data coupling with the host code (Dannert, Marek, & Rampp, 2013).

CONCLUSION

The new devices for high performance computing need standardized methods and languages that permits interoperability, easy programming and well defined interfaces for integrating the data

interchange between memory segments of the processors (CPUs) and devices. Besides, it is necessary that languages have support for working with two or more devices on parallel using the same code but running segments of high parallelism in automatically form. OpenMP is the *de facto* standard for shared memory programming model, but the support for heterogeneous devices (Gpus, accelerators, fpga, etc.) is in very early stage, the new frameworks and industrial API need help for a growing and maturing standard.

FINANCING

This research was developed with own resources, in the Doctoral thesis process at Universidad Distrital Francisco José de Caldas.

FUTURE WORKS

It is necessary to analyze the impact of frameworks for multiple devices on the same host for management problems of memory locality, unified memory between CPU and devices and I/O operations from devices using the most recent version of its standard framework. With the support of GPUs device on the following version of GCC5, it is possible to obtain a compiler performance comparison between commercial and standards open source solutions. Furthermore, it's necessary to review the impact of using cluster with multi-devices, messaging pass and MPI integration for high performance computing using the language extensions (Schaa & Kaeli, 2009).
